Abstract

This research presents an approach in the analysis of capital markets; behavioral finance. Behavioral finance is the study of the influence of the psychological factors on financial markets evolution. Financial investors are people with a very varied number of deviations from rational behavior, which is the reason why there is a variety of effects, which explain market anomalies. Classical finance assumes that investors are rational and they are focused to select an efficient portfolio, which includes a combination of asset classes chosen in such a manner as to achieve the greatest possible returns over the long term, under the terms of a tolerable level of risk. Behavioral finance paradigm suggests that investment decision is influenced in a large proportion by psychological and emotional factors.

Keywords: Capital markets, Behavioral Finance, Rational, Portfolio, Psychological and Emotional factors

Introduction

Behavioral finance studies the influence of psychological factors on financial markets evolution. In other words, financial markets inefficiency is analyzed in the light of the psychological theories and perspectives. Behavioral finance is a recent and high impact paradigm which provides an interesting alternative to classical finance. The classical finance assumes that capital markets are efficient, investors are rational and it’s not possible to outperform the market over the long-term.

Principles of behavioral finance include heuristics and biases, overconfidence, emotion and social forces. A very important step for an investor is to understand his financial personality. In other words, in the posture of investor is vitally important to understand why you make certain financial decisions or how you are likely to react in common conditions of uncertainty. This form of analysis is useful in an attempt to understand how you can temper the irrational components of investment decisions while still satisfying your individual preferences and requirements.

Behavioral finance provides a different perspective, very complex and unconventional. Behavioral finance paradigm suggests that investment decision is influenced in a large proportion by psychological and emotional factors. Human emotional complexity includes the following primary feelings: fear, panic, anxiety, envy, euphoria, greed, satisfaction, ambition or vanity. These emotions interfere in certain proportions in a financial investment decision making (Birau, 2011a).

Beyond the theoretical explanation of the question, obvious financial markets imperfections make wonder if the classical financial theory is not just an unrealistic and incomplete solution to a complex and constantly changing problem. Most of the financial market differences cannot be explained using traditional models. Behavioral finance makes it easy to explain why the individual has taken a specific
decision, but did not find as easily an explanation about how future decisions will be.

Classical finance has as a cornerstone the Efficient Markets Hypothesis, according to whom, since everyone has access to the same information, it is impossible to regularly beat the market, because that stock prices are, in fact, efficient, reflecting everything we know as investors. A market in which prices always “fully reflect” available information is called efficient. Synthesizing, Efficient Markets Hypothesis assume that capital market are informational efficient.

According to Fama (1998), the father of efficient market hypothesis : “market efficiency is going to survive the challenge from the literature on long-term return differences. Consistent with the market efficiency hypothesis that the anomalies are chance results, apparent overreaction to information is about as common as under reaction, and postevent continuation of pre-event abnormal returns is about as frequent as post-event reversal. Most important, consistent with the market efficiency prediction that apparent anomalies can be due to methodology, most long-term return anomalies tend to disappear with reasonable changes in technique”. In contrast behavioral finance assumes that in some circumstances it is informational inefficient. (Ritter, J., 2003)

The purpose of this article is to have an insight into how the influence of psychology on the behavior of the investors can explain capital markets imperfections. Human nature is perfectible, but it is not perfect. Investors are people with many deviations from rational behavior, which often make illogical decisions. In the existing global financial perspective, the major influence of psychological factors in investment decision-making is undeniable.

**Finance paradigm and its imperfections**

Classical finance assumes that investors are rational and they are focused to select an efficient portfolio, which includes a combination of asset classes chosen in such a manner as to achieve the greatest possible returns over the long term, under the terms of a tolerable level of risk.

The concept of efficient market was anticipated long time before through the work of researchers such as G. Cardano (1564), R. Brown (1828), J. Regnault (1863), Rayleigh (1880), John Venn (1888), L. Bachelier (1900), Einstein (1905), F.W.Taussing (1921), J.M. Keynes (1923), A. Cowles (1933), M. Friedman (1953), M.G. Kendall (1953) and P.A. Samuelson (1965). Interestingly, in most cases, the subject of the research not targeted financial market or stock exchanges.

Essence of the Efficient Markets Hypothesis is considered as any information which is available to all investors or market participants, so stock prices always incorporate and reflect all relevant information. In consequence, the price of a stock should reflect the knowledge and expectations of all investors or market participants.

In the paper “Random Walks in Stock Market Prices” published in 1965, Eugene Fama suggested that: ”an efficient market is defined as a market where there are large numbers of rational, profit-maximizers actively competing, with each trying to predict future market values of individual securities, and where important current information is almost freely available to all participants”.

106
In terms of taking into consideration an alternative theory, Fama left the impression that such an idea is just one of consistent overreaction or underreaction, and stated that "since the anomalies literature has not settled on a testable alternative to market efficiency, to get the ball rolling, I assume that reasonable alternatives must predict either over-reaction or under-reaction."

In an efficient market at any point in time the actual price of a security will be a good estimate of its intrinsic value. Technically, in an efficient market, no investment strategy can earn excess risk-adjusted average returns, or average returns greater than are warranted for its risk (Barberis, N., Thaler, R., 2003).

Around the 1970s, the idea of market efficiency was accepted and supported enthusiastically in academic circles mainly due to arbitrage assumptions. Empirical studies have shown that this vision is unrealistic, because the lack of an investment strategy does not imply the absence of mispricing. In what concerning the opposite situation, limits to arbitrage can generate severe mispricing. In general arbitrage is typically defined as “the simultaneous purchase and sale of the same, or essentially similar, security in two different markets for advantageously different prices” (Sharpe, W., Alexander, G., 1990).

Gromb and Vayanos in their suggested that understanding why anomalies exist and are not eliminated requires a careful study of the process of arbitrage: who are the arbitrageurs, what are the constraints and limitations they face, and why arbitrage can fail to bring prices close to the fundamental values implied by standard models.

Allocation efficiency implies the optimum allocation of resources according to the concept of Pareto optimality and it is established so that it is equivalent to the marginal rates of return, adjusted for risk, with respect to all market participants. In other words, a market is organizational efficient if it is not possible to change the allocation of resources in such a way as to make some participants better off without making others worse off. Operational efficiency is reached when the transfer cost of financial funds are reasonable, being determined by a high number of participants on the market and by the mechanism which contributes to the assurance of equilibrium prices.

A market is efficient with respect to a set of information if it is impossible to make economic profits by trading on the basis of this information set (Ross, 1987). In other words, no arbitrage opportunities, after costs, after risk premium can be achieved using ex ante information as a result of the fact that all information available at any time is fully reflected in current prices. According to Statman: “Stock market efficiency has two meanings. To some, market efficiency means that there is no systematic way to beat the market. To others, it means that security prices are rational – that is, reflect only “fundamental” or “utilitarian” characteristics, such as risk, but not “psychological” or “value-expressive” characteristics, such as sentiment.”

Malkiel suggested the following definition: “A capital market is said to be efficient if it fully and correctly reflects all relevant information in determining security prices. Formally, the market is said to be efficient with respect to some information set...if security price would be unaffected by
revealing that information to all participants. Moreover, efficiency with respect to an informational set…implies that it is impossible to make economic profits by trading on the basis of that informational set.”

In this article focus is on the idea of informational efficiency. A market in which prices always “fully reflect” available information is called efficient.

In an informational efficient market, price changes cannot be forecasted if they fully incorporate the expectations and information of all market participants. In other words, if stocks were predictable and not uncertain, it would therefore be possible to take action in order to generate systematic gains. But exactly these issues made the stocks uncertain and unpredictable. The prices depend on a summation of so many small and relatively independent sources of variation that the result is like a random walk (Samuelson, P., 1965).

According to the Efficient Markets Hypothesis, the weak form efficiency is distinguished by the fact that current price of a financial asset reflects all the historical financial information available on the market. Houthakker and Williamson consider that if the weak form of the efficient market holds, prices will exhibit a “random walk”, which is a representative concept of probability theory.

The semi-strong form efficiency is characterized by the fact that share prices adjust to publicly available new information very rapidly and in an unbiased manner, such that no excess returns can be earned by trading on that information. In this case, neither fundamental analysis nor technical analysis techniques will be able to reliably produce excess returns (Birau, 2011b).

In addition, strong form efficiency includes both semi-strong form efficiency and weak form efficiency. Specifically, share prices reflect all information, public and private, but none of these can earn excess returns. In a civilized world, the legal system prevents private information to become public, using various legislative and institutional barriers. Only in a disorganized system which completely ignores legal restrictions could be this possible.

Efficient Markets Hypothesis highlight the fact that absolute rationality of the capital market characterized by the fact that all investors are rational it is a statement of fact and must be generally accepted. The question is whether investors can behave in a rational way in the context of an irrational world? Many years ago, John Maynard Keynes provided a simply and shattering realistic answer to this dilemma. He suggested in an aphoristic manner that the market can remain irrational longer than an investor can remain solvent.

Behavioral finance - an original approach to capital markets

The modern finance has registered remarkable progress in the last decades. Behavioral finance is a new approach to capital markets, having an important role in financial decision making process. Decision making related with behavioral finance that can be defined as the process of choosing a particular investment alternative from a number of alternatives. It is an activity that follows after proper evaluation of all the alternatives (Mathews, J., 2005).

In the 1960s cognitive psychology began to shed more light on the brain as an information processing device. Psychologists in this field, such as Ward Edwards, Amos Tversky and Daniel
Kahneman began to compare their cognitive models of decision-making under risk and uncertainty to economic models of rational behavior. In mathematical psychology, there is a longstanding interest in the transitivity of preference and what kind of measurement scale utility constitutes (Luce, 2000).

In 1979, Kahneman and Tversky wrote Prospect theory: An Analysis of Decision under Risk, an important paper that used cognitive psychology to explain various divergences of economic decision making from neo-classical theory. According to Sewell (2005), behavioral finance is the study of the influence of psychology on the behavior of financial practitioners and the subsequent effect on markets.

Barberis and Thaler (2001) in their paper consider that behavioral finance has two building blocks: limits to arbitrage, which argues that it can be difficult for rational traders to undo the dislocations caused by less rational traders and psychology, which catalogues the kinds of deviations from full rationality we might expect to see.

Fromlet (2001) gave definition: “behavioral finance closely combines individual behaviorand market phenomena and uses knowledge taken from both the psychological field and financial theory”.

Behavioral finance must be understood as an area in full development with major implications for the manner in which the investment process is directed. In other words, behavioral finance is a broad visions paradigm which is trying to understand and to forecast financial markets based on psychological and emotional implications.

According to some researchers, behavioral finance states the features of interpretation and action based on the data for organized investing decisions by individuals. In Thaler opinion, behavioral finance defines that some of the economic factors sometimes may not treat rationality based on the assumption and Olsen also says, behavioral finance is the psychological decision process in recognition and prediction of financial markets (A. Talangi, 2004).

Behavioral finance represents an area of research that attempts to understand and explain how reasoning or cognitive errors influence investor decisions and stock market prices. Thus, behavioral finance combines principles from the fields of individual and social psychology with classical financial theory to understand and highlight the performance of stock markets.

It can also be said as behavioral finance it is an alternative solution to the difficulties faced by the classical theory in explaining certain financial phenomena. In deep contradiction to the classical paradigm, behavioral finance assumes that investors may be irrational in their reactions to new information and investment decisions. In these conditions, it can be difficult, if not even impossible for rational traders to undo the mispricing caused by irrational investors due to existing limits of arbitrage. Actually, the limits to arbitrage theory demonstrates that if irrational traders cause deviations from fundamental value, rational traders will often be powerless to do anything about it.

Shefrin states that there are three themes predominate in behavioral finance and economics:

a) Heuristics: Investors often make decisions based on approximate rules of thumb, without relying on alogical reasoning.

b) Framing: The collection of anecdotes and stereotypes that make up the mental
emotional filters individuals rely on to understand and respond to events.
c) Market inefficiencies: These particular characteristic includes mispricings, non-rational decision making, and return anomalies.

Human emotional complexity includes the following primary feelings: fear, panic, anxiety, envy, euphoria, greed, satisfaction, ambition or vanity. Very likely that all these emotions interfere in certain proportions in a financial investment decision making

Tilson have identified some extremely varied Common Mental Mistakes, they are:

a) Overconfidence
b) Projecting the immediate past into the distant future
c) Herd-like behavior (social proof), driven by a desire to be part of the crowd or an assumption that the crowd is omniscient
d) Misunderstanding randomness which refers to seeing patterns that don’t exist
e) Commitment and consistency bias
f) Fear of change, resulting in a strong bias for the status quo
g) “Anchoring “on irrelevant data
h) Excessive aversion to loss
i) Using mental accounting to treat some money (such as gambling winnings or an unexpected bonus) differently than other money
j) Allowing emotional connections to over-ride reason
k) Fear of uncertainty
l) Embracing certainty
m) Overestimating the likelihood of certain events based on very memorable data or experiences
n) Becoming paralyzed by information overload

Behavioral finance realizes financial theory to practical investment analysis in order to provide a means of understanding the financial market complex situations. In fact, the main idea is finding an explanation for market inefficiencies such as: mispricing, irrational investment decision making and returns differences. The influence of informational asymmetry, psychological, sociological and demographic structures can represent up to a certain level, a relevant answer to financial market anomalies. Investors are different because of the numerous factors, such as: socio-economic background, financial context, level of education, religion, age, sex, traditions, ethnicity, marital status, and so on and influences their investment decisions in a dramatic proportion. An optimum
investment decision it cannot be achieved if the investor ignore these factors.

Behavioral finance is focusing on the cognitive psychology suggest that the investment decision-making process may be analyzed successfully through the following variables: overconfidence, herding complex, overreaction, conservatism, preconceived ideas, excessive optimism, representativeness, irrationality or rational way of thinking and the impact of media channels.

Empirical studies have shown that investors are overconfident in their judgments and due to this seemingly insignificant appearance they make mistakes when perceive information and form their beliefs. Also, investors overreact in certain circumstances or they act under the impulse of some beliefs such as those mentioned above. If the stock market behaved like a mechanically imperfect roulette wheel, people would notice the imperfections and, by acting on them, remove them. This rationale is appealing, if for no other reason than its value as a counterweight to the popular view of stock market “irrationality,” but it is obviously incomplete [Roberts, H., 1959].

Richard Thaler provides in his 1999 article, “The End of Behavioral Finance,” published in the Financial Analysts Journal, a simple and very relevant model for understanding the significance attained by behavioral finance paradigm: “Suppose a market has two kinds of investors: rational investors who behave like agents in economics textbooks, and quasi-rational investors, people who are trying to make good investment decisions but make predictable mistakes. Suppose also that two assets in this market, X and Y, are objectively worth the same amount but cannot be transformed from one into the other. Finally, assume that the quasi’s think X is worth more than Y, an opinion that could change (quasi’s often change their minds) while rational know that X and Y are worth the same. What conditions are necessary to assure that the prices of X and Y will be the same, as they would be in a world with only rational investors?”

The above question is complex, but some of the essential conditions are the following. In dollar-weighted terms, such a market cannot have too many quasi’s (in order for the rational investor to be marginal), market must allow costless short selling (so that if prices get too high, the rationals can drive them down), only rational investors can sell short; otherwise, the quasi’s will short Y when the two prices are the same because they believe X is worth more than Y, at some date T the true relationship between X and Y must become clear to all investors and at last the rational must have long horizons, long enough to include date T. These conditions are tough to meet.

**Conclusion**

Behavioral finance is creating a revolution in financial theory. The combination of financial theory with other social sciences resulted in the appearance of behavioral finance. This is a relatively young and promising field of modern finance which has registered remarkable progress in the last decades. Behavioral finance highlights the psychological edge of investment decision making process, in strong contradiction to the Efficient Markets Hypothesis.

The most important issue in efficient market theory is that it is not possible to outperform the market over the long-term. An efficient capital market is characterized by the fact that information is available to all investors or market participants, so stock prices always incorporate and reflect all relevant
information. Due to this issue, the price of a stock should reflect the knowledge and expectations of all investors or market participants.

It is certainly not possible to separate an investor’s personality and the investment decisions that they may make. Thus, it cannot be ignored the importance of understanding the individual financial behavior of capital market investors.

There is no need to make extensive psychological assumptions to understand investment decision as that does not focus strictly on financial theory. Investors, both amateurs and professionals, make their choices in a way that it cannot be considered absolutely rational. There are indisputable arguments in favor of both theories as both present certain limits. Behavioral finance is not a perfect replacement to classical finance paradigm, but it is an alternative solution to the difficulties faced by the traditional theory in explaining certain financial phenomena. Probably the only undeniable truth is that financial markets are extremely complex and unpredictable to believe that we can understand perfectly their mechanism. (Birau, 2011a).
